Can a dynamic equivalent circuit be used to model supercapacitors?

The aim of this study was to demonstrate that the dynamic equivalent circuit can be used to model the behaviour of supercapacitors if one allows for an interpretation in terms of a distribution of relaxation times.

What is full supercapacitor dynamic model (FSC)?

Full Supercapacitor Dynamic Model (FSC) In this case, the voltage across the supercapacitor is different from the voltage across the output of the first DC-DC converter, and this difference depends on the current drawn from the PV source.

How can a supercapacitor be interpreted in a consistent manner?

Such a model can be used to explain the most common features of a supercapacitor in a consistent manner. In the time domain, it is shown that the time-dependent charging rate and the self-discharge of a supercapacitor can both be interpreted in this model with either a few or a continuous distribution of relaxation times.

What is the role of relaxation times in a supercapacitor model?

Distribution of relaxation times provides an indicator of charge dynamics at the electrodes. Both time dynamics (charging and self-discharging) and impedance spectroscopy can be studied within the model. Supercapacitors are often modelled using electrical equivalent circuits with a limited number of branches.

Can supercapacitors explain long-term dynamics?

Supercapacitors are often modelled using electrical equivalent circuits with a limited number of branches. However, the limited number of branches often cannot explain long-term dynamics, and one therefore has to resort to more computationally challenging basic models governing diffusion and drift of ions.

What is an electrochemical double layer capacitor?

Introduction Electrochemical double layer capacitors, often called supercapacitors, were patented in 1957 and later commercialized. Supercapacitors are based on porous carbon immersed in an electrolyte, where the ions can form an electrical double layer which aids in storing electrical charge.
