What does internal resistance mean in a battery?

Internal resistance can be thought of as a measure of the "quality" of a battery cell. A low internal resistance indicates that the battery cell is able to deliver a large current with minimal voltage drop, while a high internal resistance indicates that the battery cell is less able to deliver a large current and experiences a larger voltage drop.

How does internal resistance affect the performance of a battery cell?

The internal resistance of a cell can affect its performance and efficiency, and it is typically higher at higher current densities and lower temperatures. The open circuit voltage  $E$  [V] of a battery cell is the voltage of the cell when it is not connected to any external load.

How to calculate the internal resistance of a battery cell?

We aim to calculate the internal resistance of the cell at approximately 47 % state of charge (SoC). Step 1. Calculate the discharge capacity of the battery cell for 47 % SoC. Since the nominal capacity of the battery cell is 3200 mA, which corresponds to 100% SoC, at 47% SoC, the battery cell capacity would be:  $0.47 \times 3200 = 1504 \text{ mAh} \approx 1500 \text{ mAh}$

What if the internal resistance of a battery cell is not provided?

If the internal resistance of the battery cell is not provided by the manufacturer, as we'll see in this article, using the discharge characteristics of the battery cell, we can calculate the internal resistance of the battery cell, for a specific state of charge value.

What is the resistance of a battery pack?

The resistance of a battery pack depends on the internal resistance of each cell and also on the configuration of the battery cells (series or parallel). The overall performance of a battery pack depends on balancing the internal resistances of all its cells.

How do you find the internal resistance of a battery pack?

If each cell has the same resistance of  $R_{\text{cell}} = 60 \text{ m}\Omega$ , the internal resistance of the battery pack will be the sum of battery cells resistances, which is equal with the product between the number of battery cells in series  $N$  and the resistance of the cells in series  $R_{\text{cell}}$ .  $R_{\text{pack}} = N \times R_{\text{cell}} = 3 \times 60 = 180 \text{ m}\Omega$
