

How to calculate the DC internal resistance of a battery pack

How do you measure the internal resistance of a battery?

A key parameter to calculate and then measure is the battery pack internal resistance. This is the DC internal resistance (DCIR) and would be quoted against temperature, state of charge, state of health and charge/discharge time. Symbolically we can show a cell with the internal resistance as a resistor in series.

What is the resistance of a battery pack?

The resistance of a battery pack depends on the internal resistance of each cell and also on the configuration of the battery cells (series or parallel). The overall performance of a battery pack depends on balancing the internal resistances of all its cells.

How do you find the internal resistance of a battery pack?

If each cell has the same resistance of $R_{\text{cell}} = 60 \text{ m}\Omega$, the internal resistance of the battery pack will be the sum of battery cells resistances, which is equal with the product between the number of battery cells in series N and the resistance of the cells in series R_{cell} . $R_{\text{pack}} = N \times R_{\text{cell}} = 3 \times 0.06 = 180 \text{ m}\Omega$

Why is internal resistance important in a battery pack?

High internal resistance in a pack can make it less efficient, reduce its range, and create too much heat in EVs, which can be dangerous and shorten the battery's life. Therefore, calculating and reducing the internal resistance of battery packs is crucial in designing efficient, safe, and long-lasting battery systems.

How to calculate the internal resistance of a battery cell?

We aim to calculate the internal resistance of the cell at approximately 47 % state of charge (SoC). Step 1. Calculate the discharge capacity of the battery cell for 47 % SoC. Since the nominal capacity of the battery cell is 3200 mA, which corresponds to 100% SoC, at 47% SoC, the battery cell capacity would be: $0.47 \times 3200 = 1504 \text{ mAh} \approx 1500 \text{ mAh}$

How do you calculate internal resistance?

This is the formula for calculating internal resistance: $ISR = (V_1 - V_2) / I_{\text{load}}$ The measure of Internal resistance is one of the most important measurements of a battery you can have. With the internal resistance, you can calculate what the exact voltage drop will be at a given current.
