What is a rectifier & ups module?

UPS Module: It consists of UPS (without Battery). Depending upon the configuration selected, one or more UPS modules can be employed. The job of the Rectifier is to convert AC to DC current, by means of a 6- or 12-pulse thyristor to provide supply to both Battery and Inverters.

How does a thyristor rectifier work?

The Rectifier's function is to convert alternating power to direct current using a 6- or 12-pulse thyristor to supply both the battery and the inverter. The main current distortion is roughly half that of a 6-pulse thyristor rectifier when employing a 12-pulse thyristor rectifier. 2). Inverter

How does an ups rectifier work?

UPS rectifiers can accept wide input voltage fluctuations, meaning the system can handle overloads or surges without having to engage the batteries. The batteries in a UPS system provide emergency power when the mains supply fails. Either the rectifier or a separate charger ensures that the batteries are always charged.

How a rectifier-inverter system works?

The rectifier-inverter system provides alternating current to the load while simultaneously charging the battery. When there is a break in the operation because its battery is always linked to the inverter through which the load is supplied, online UPSs may deliver uninterruptible power without any transfer delay.

What is battery pack assembly?

Battery Pack Assembly: A Comprehensive Process In general, assembling a battery pack is a systematic process that involves moving from cells to modules and eventually to the battery pack. Each step plays a crucial role in ensuring the efficient operation of the battery system.

How do battery modules work?

This is where battery modules come into play. Cells are initially connected and housed within frames to form these modules. Various battery assembly equipment are used to form packs from cells and provide an additional layer of protection, shielding cells from external factors such as heat and vibration.
